Document for First Edition	End-user documentation for Image Injection feature

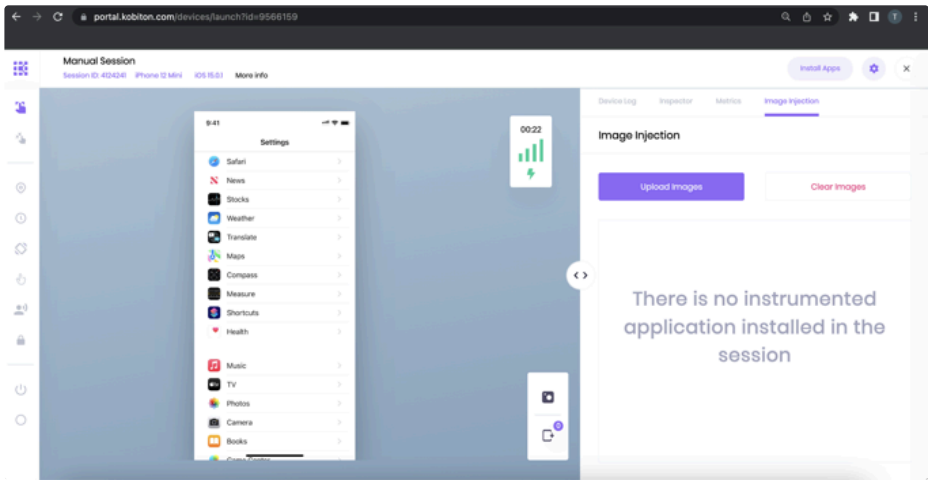
In v3.20 release, we're introducing a new UI for Image Injection feature .

Overview of Image Injection Feature

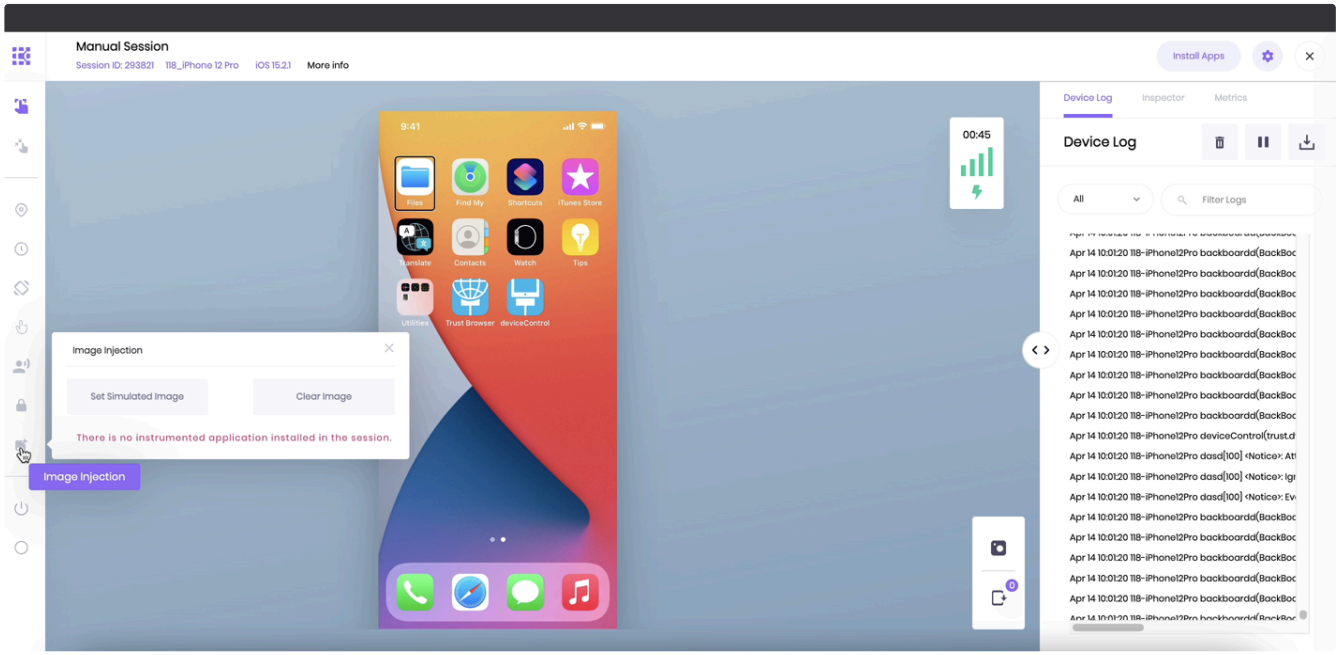
- Users can inject an image into an open device to simulate camera use. This is useful for testing application actions such as barcode reader or bank check scanning apps.
- When uploading an image, the maximum size is 5MB and it can be in JPG, JPEG, or PNG format.

Why we have this enhancement:

Current UI:



New UI - a pop up modal on the left side



to keep two sides' data of the screen consistent:

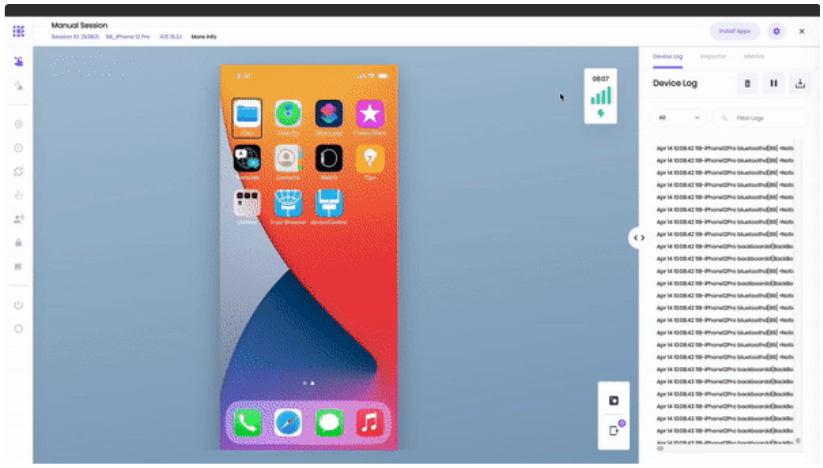
- The Right Menu should only keeping the device's log
- The Left Menu should indicate all the action steps of the user during a manual session.

How does it works

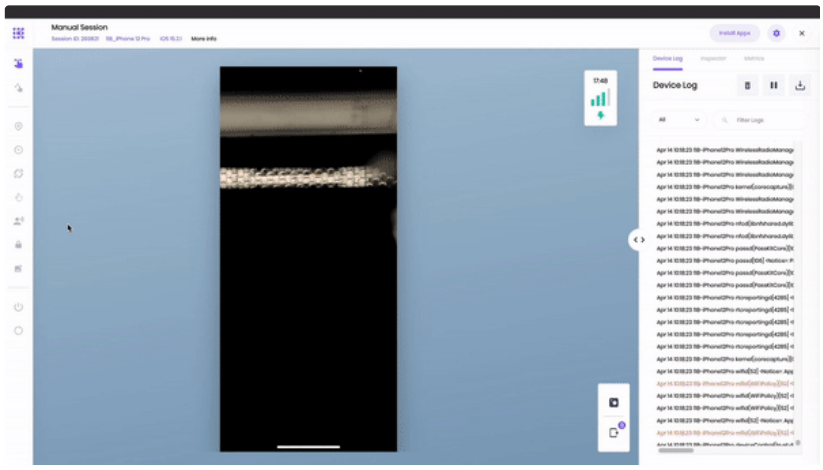
This feature is only available for the latest Kobiton.

In manual session

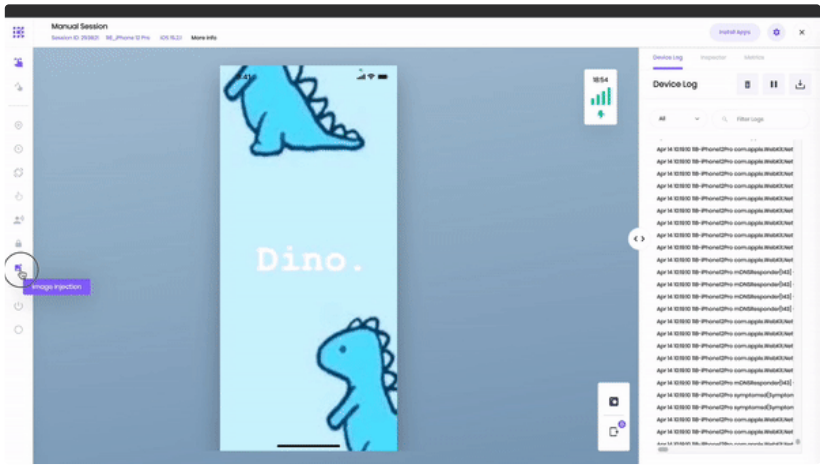
1. Install your application which needs image injection. Remember to toggle on the instrumentation option.



2. The image injection feature is available after installing an app with instrument mode. While in your app, open the Image Injection Pop Up and import your images. Click **Inject** to use that image for the camera.

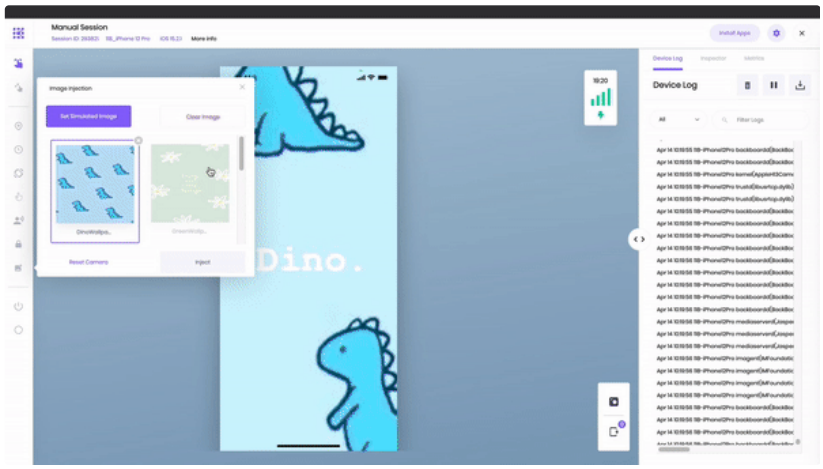


3. You can import one or many images at one time into your gallery.

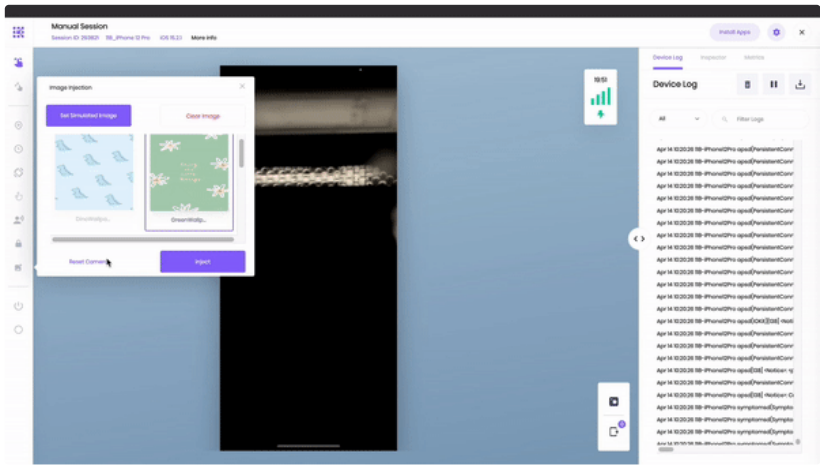


4. To change your current injected image, click Reset Camera & choose another image, then click Inject to use it for the camera.

Your Camera will use your injected image until you click Reset Camera to release it.

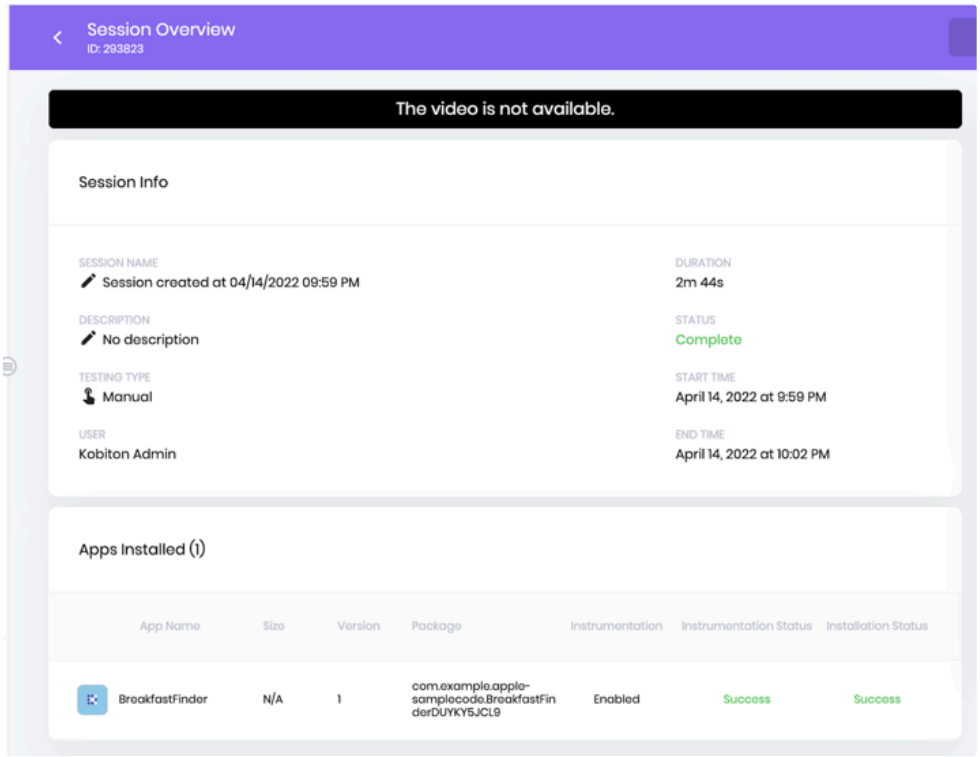


5. To delete images in your gallery, you can delete one by one image by select that image then click Clear Image. To delete all images, simply click Clear Image.

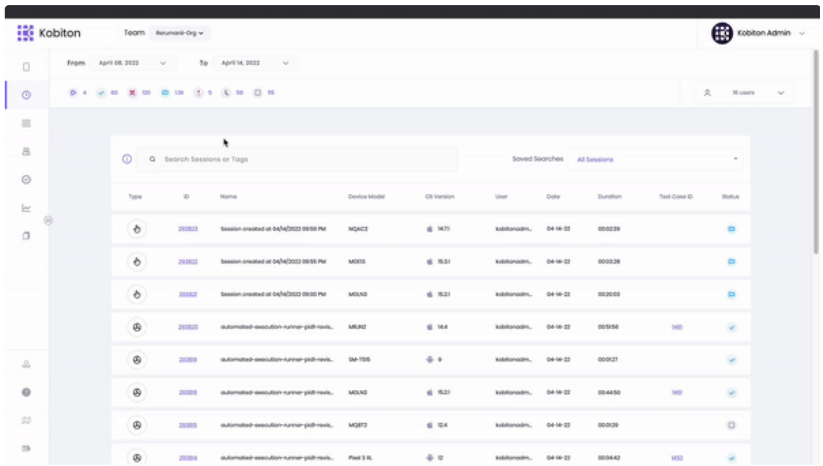


In Session Overview

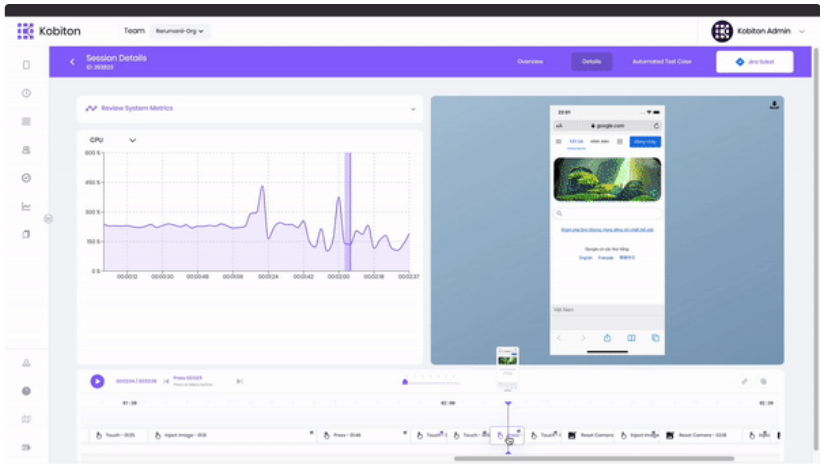
1. There is a table Apps Installed lists all the Instrumentation Status & Installation Status for debugging.



2. When go into Session Details, we will have an additional popup along every steps with injected image. User can click to see the injected image even it's not included in the screenshot.



3. This pop-up also indicates the life-cycle of an injected image in a session. The camera will keep using the injected image until there's a Reset Camera step. Please note that the screenshot of the device screen cannot remove the injected image in "Reset Camera" step but it's been deleted in the system.



Limitations

- We currently support image injection on iOS and Android devices, but there are some limitations listed below:
  - Images cannot be injected into several applications due to the number of support needed library is huge - We currently only use the most common libraries and we will help to investigate case-by-case if any customer encounters issues when using Image Injection Feature.
  - When using the instrumenting app on dC Android devices, the injected image is rotated.
  - App instrumentation is not working on a few Android applications, especially those applications that was obfuscated with DexGuard. Make sure to upload and use a non-obfuscated app version in Kobiton
  - The injected image is zoom-ed a little when in-use, compared to the actual size
  - We will add image's size & name for the Injected Image Pop-up in later phase.
